M68HC08 Integer Math Routines

By Mark Johnson
CSIC Applications Engineering
Austin, Texas

Introduction

This application note discusses six integer math subroutines⁽¹⁾ that take advantage of one of the main CPU enhancements in the 68HC08 Family of microcontroller units (MCU). Each of these subroutines uses stack relative addressing, an important CPU enhancement.

Although the 68HC08 MCU is a fully upward-compatible performance extension of the 68HC05 MCU Family, users familiar with the 68HC05 should have little difficulty implementing the 68HC08 architectural enhancements. For instance, storage space for local variables needed by a subroutine can now be allocated on the stack when a routine is entered and released on exit. Since this greatly reduces the need to assign variables to global RAM space, these integer math routines are implemented using only 10 bytes of global RAM space. Eight bytes of global RAM are reserved for the two 32-bit pseudo-accumulators, INTACC1 and INTACC2. The other 2 bytes assigned to SPVAL are used by the unsigned 32 x 32 multiply routine to store the value of the stack pointer.

INTACC1 and INTACC2 are defined as two continuous 4-byte global RAM locations that are used to input hexadecimal numbers to the

None of the six subroutines contained in this application note check for valid or non-zero numbers in the two integer accumulators. The user is responsible for ensuring that proper values are placed in INTACC1 and INTACC2 before the subroutines are invoked.

subroutines⁽¹⁾ and to return the results. For proper operation of the following subroutines, these two storage locations must be allocated together, but may be located anywhere in RAM address space. SPVAL may be allocated anywhere in RAM address space.

Software Description

Unsigned 16×16 Multiply (UMULT16)

Entry conditions:

INTACC1 and INTACC2 contain the unsigned 16-bit numbers to be multiplied.

Exit conditions:

INTACC1 contains the unsigned 32-bit product of the two integer accumulators.

Size:

94 bytes

Stack space:

9 bytes

Subroutine calls:

None

Procedure:

This routine multiplies the two leftmost bytes of INTACC1 (INTACC1 = MSB, INTACC1 + 1 = LSB) by the two leftmost bytes of INTACC2 (INTACC2 = MSB, INTACC2 + 1 = LSB). (MSB is the acronym for most significant byte and LSB stands for least significant byte.) Temporary stack storage locations 1,SP-5,SP are used to hold the two intermediate products. These intermediate products are then added together and the final 32-bit result is stored in INTACC1 (INTACC1 = MSB, INTACC1 + 3 = LSB). This process is illustrated in **Figure 1** and in **Figure 2**.

AN1219 — Rev. 1.0

^{1.} The 32 x 16 unsigned divide algorithm was based on the algorithm written for the M6805 by Don Weiss and was modified to return a 32-bit quotient. The table lookup and interpolation routine was written by Kevin Kilbane and was modified to interpolate both positive and negative slope linear functions.

Figure 1. Unsigned Multiply 16 x 16 Equation

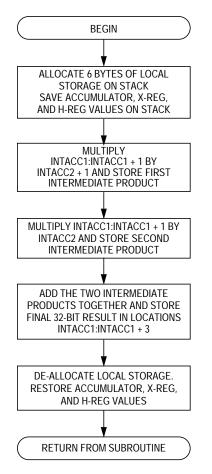

Figure 2. Unsigned 16 × 16 Multiply

Unsigned 32 × 32 Multiply (UMULT32)

Entry conditions:

INTACC1 and INTACC2 contain the unsigned 32-bit numbers to be multiplied.

Exit conditions:

INTACC1 concatenated with INTACC2 contains the unsigned 64-bit result.

Size:

158 bytes

Stack space:

38 bytes

Subroutine calls:

None

Procedure:

This subroutine multiplies the unsigned 32-bit number located in INTACC1 (INTACC1 = MSB, INTACC1 + 3 = LSB) by the unsigned 32-bit number stored in INTACC2 (INTACC2 = MSB, INTACC2 + 3 = LSB). Each byte of INTACC2, starting with the LSB, is multiplied by the 4 bytes of INTACC1 and a 5-byte intermediate product is generated. The four intermediate products are stored in a 32-byte table located on the stack. These products are then added together and the final 8-byte result is placed in INTACC1:INTACC2 + 3 (INTACC1 = MSB, INTACC2 + 3 = LSB). An illustration of this mathematical process is shown in **Figure 3** and **Figure 4**.

7.11.2.10

INTACC1 = Multiplier INTACC2 = Multiplicand INTACC1 × INTACC2 INTACC1:INTACC1 + 1:INTACC1 + 2:INTACC1 + 3 × INTACC2:INTACC2 + 1:INTACC2 + 2:INTACC2 + 3 (INTACC1:INTACC1 + 1:INTACC1 + 2:INTACC1 + 3)(INTACC2 + 3)(INTACC1:INTACC1 + 1:INTACC1 + 2:INTACC1 + 3)(INTACC2 + 2) (INTACC1:INTACC1 + 1:INTACC1 + 2:INTACC1 + 3)(INTACC2 + 1) (INTACC1:INTACC1 + 1:INTACC1 + 2:INTACC1 + 3)(INTACC2) IR06 R07⁽¹⁾ 0 0 IR04 IR05 0 IR03 0 0 IR12 IR13 IR14 IR15 **IR16** 0 IR22 0 IR21 IR23 IR24 **IR25** 0 IR30 IR31 IR32 IR33 IR34 0 0

^{1.} The intermediate result (IR) tags are temporary storage locations on the stack, not hard-coded locations in RAM.

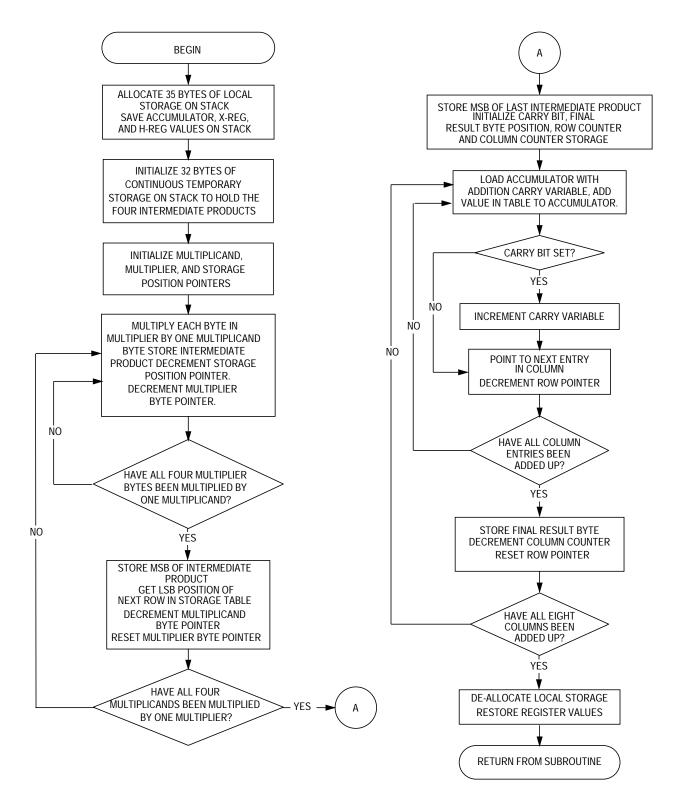

Figure 4. Unsigned 32 × 32 Multiply

AN1219 — Rev. 1.0

Signed 8 × 8 Multiply (SMULT8)

Entry conditions:

INTACC1 and INTACC2 contain the signed 8-bit numbers to be multiplied.

Exit conditions:

The two leftmost bytes of INTACC1 (INTACC1 = MSB, INTACC1 + 1 = LSB) contain the signed 16-bit product.

Size:

57 bytes

Stack space:

4 bytes

Subroutine calls:

None

Procedure:

This routine performs a signed multiply of INTACC1 (MSB) and INTACC2 (MSB). Before multiplying the two numbers together, the program checks the MSB of each byte and performs a two's complement of that number if the MSB is set. One byte of temporary stack storage is used to hold the result sign. If both of the numbers to be multiplied are either negative or positive, the result sign LSB is cleared or it is set to indicate a negative result. Both numbers are then multiplied together and the results are placed in the two left-most bytes of INTACC1 (INTACC1 = MSB, INTACC1 + 1 = LSB). The routine is exited if the result sign storage location is not equal to one or the result is two's complemented and the negative result is stored in locations INTACC1 and INTACC1 + 1.

INTACC1 = Multiplier INTACC2 = Multiplicand

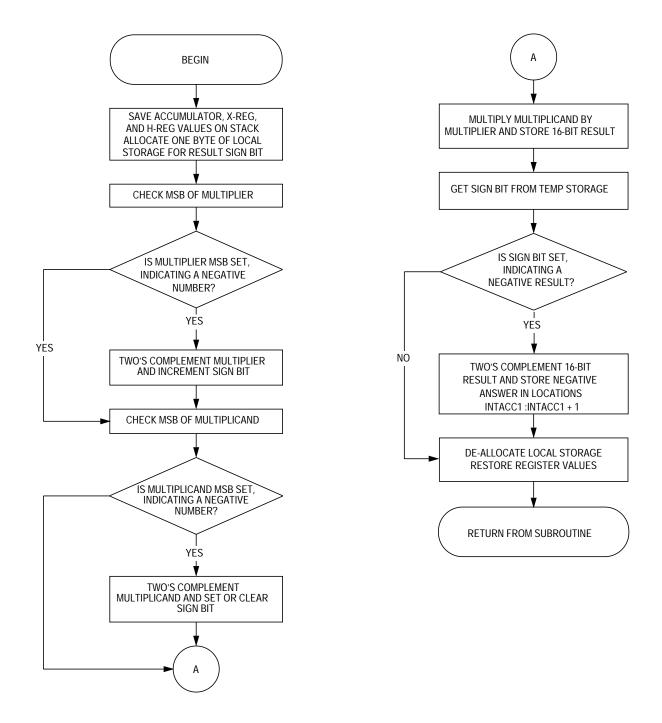

Figure 5. Signed 8 × 8 Multiply

AN1219 — Rev. 1.0

B MOTOROLA

Signed 16 × 16 Multiply (SMULT16)

Entry conditions:

INTACC1 and INTACC2 contain the signed 16-bit numbers to be multiplied.

Exit conditions:

INTACC1 contains the signed 32-bit result.

Size:

83 bytes

Stack space:

4 bytes

Subroutine calls:

UMULT16

Procedure:

This routine multiplies the signed 16-bit number in INTACC1 and INTACC1 + 1 by the signed 16-bit number in INTACC2 and INTACC2 + 1. Before multiplying the two 16-bit numbers together, the sign bit (MSB) of each 16-bit number is checked and a two's complement of that number is performed if the MSB is set. One byte of temporary stack storage space is allocated for the result sign. If both 16-bit numbers to be multiplied are either positive or negative, the sign bit LSB is cleared, indicating a positive result, but otherwise the sign bit LSB is set. Subroutine UMULT16 is called to multiply the two 16-bit numbers together and store the 32-bit result in locations INTACC:INTACC1 + 3 (INTACC1 = MSB, INTACC2 = LSB). The routine is exited if the result sign LSB is cleared or the result is two's complemented by first one's complementing each byte of the product and then adding one to that result to complete the two's complement. The 32-bit negative result is then placed in INTACC1.

INTACC1 = Multiplier INTACC2 = Multiplicand

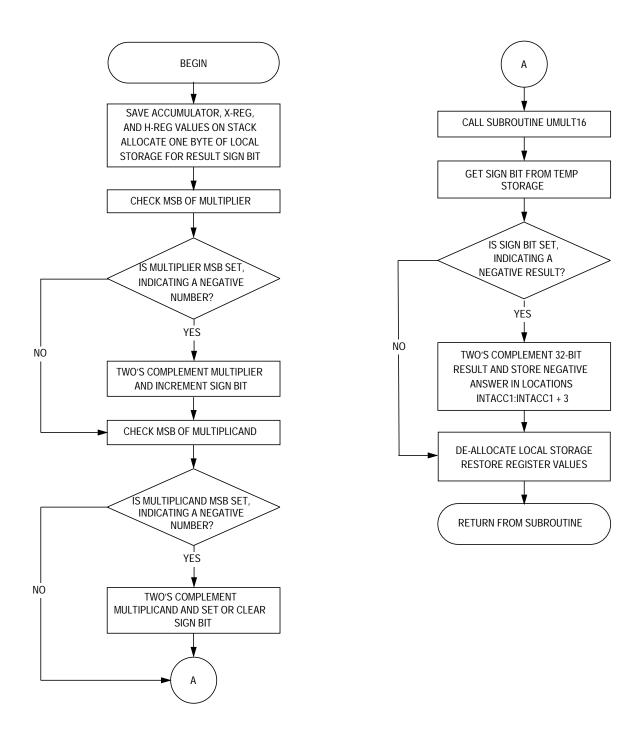

Figure 6. Signed 16×16 Multiply

32 × 16 Unsigned Divide (UDVD32)

Entry conditions:

INTACC1 contains the 32-bit unsigned dividend and INTACC2 contains the 16-bit unsigned divisor.

Exit conditions:

INTACC1 contains the 32-bit quotient and INTACC2 contains the 16-bit remainder.

Size:

136 bytes

Stack space:

6 bytes

Subroutine calls:

None

Procedure:

This routine takes a 32-bit dividend stored in INTACC1:INTACC1 + 3 and divides it by the divisor stored in INTACC2:INTACC2 + 1 using the standard shift-and-subtract algorithm. This algorithm first clears the 16-bit remainder, then shifts the dividend/quotient to the left one bit at a time until all 32 bits of the dividend have been shifted through the remainder and the divisor is subtracted from the remainder. (See illustration.) Each time a trial subtraction succeeds, a 1 is placed in the LSB of the quotient. The 32-bit quotient is placed in locations INTACC1 = MSB:INTACC1 + 3 = LSB and the remainder is returned in locations INTACC2 = MSB, INTACC2 + 1 = LSB.

Before subroutine is executed:

INTACC1	INTACC1 + 1	INTACC1 + 2	INTACC1 + 3	INTACC2	INTACC2 + 1
Dividend MSB	Dividend	Dividend	Dividend LSB	Divisor MSB	Divisor LSB

During subroutine execution:

INTACC1	INTACC1 + 1	INTACC1 + 2	INTACC1 + 3	INTACC2	INTACC2 + 1
Remainder MSB	Remainder LSB	Dividend MSB	Dividend	Dividend	Dividend LSB/ Quotient MSB
– DivisorMSB	– Divisor LSB				

After return from subroutine:

INTACC1	INTACC1 + 1	INTACC1 + 2	INTACC1 + 3	INTACC2	INTACC2 + 1
Quotient MSB	Quotient	Quotient	Quotient LSB	Remainder MSB	Remainder LSB

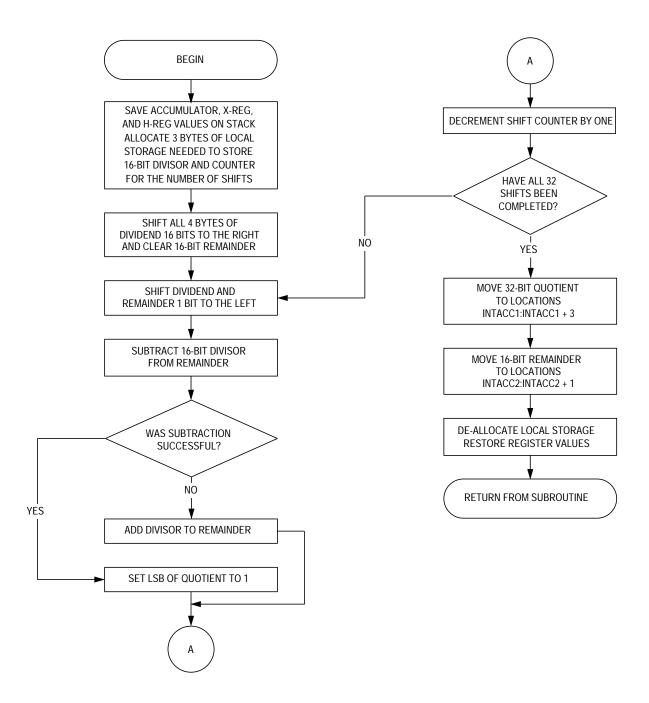

Figure 7. 32×16 Unsigned Divide

AN1219 — Rev. 1.0

Table Lookup and Interpolation (TBLINT)

Entry conditions:

INTACC1 contains the position of table ENTRY 2. INTACC1 + 1 contains the interpolation fraction.

Exit conditions:

INTACC1 + 2 : INTACC1 + 3 contains the 16-bit interpolated value (INTACC1 + 2 = MSB, INTACC1 + 3 = LSB).

Size:

125 bytes

Stack space:

4 bytes

Subroutine calls:

None

Procedure:

This routine performs table lookup and linear interpolation between two 16-bit dependent variables (Y) from a table of up to 256 entries and allowing up to 256 interpolation levels between entries. (By allowing up to 256 levels of interpolation between two entries, a 64-k table of 16-bit entries can be compressed into just 256 16-bit entries.) INTACC1 contains the position of table entry 2 and INTACC1 + 1 contains the interpolation fraction. The unrounded 16-bit result is placed in INTACC1 + 2 = MSB, INTACC1 + 3 = LSB. INTACC2 is used to hold the two 16-bit table entries during subroutine execution. The interpolated result is of the form:

Y = ENTRY1 + (INTPFRC(ENTRY2 - ENTRY1)) / 256

where:

- Y can be within the range 0 < Y < 32,767.
- INTPFRC = $(1 \le X \le 255) / 256$
- ENTRY1 and ENTRY2 can be within the range 0 < ENTRY < 32767.
- Slope of linear function can be either positive or negative.
- The table of values can be located anywhere in the memory map.

AN1219 — Rev. 1.0

Example:

Table 1. Lookup and Interpolation

	Entry Number	Y Value
	0	0
	:	:
	145	1688
ENTRY 1 \rightarrow	146	2416
ENTRY 2 \rightarrow	147	4271
	:	:
	255	0

- Find the interpolated Y value half way between entry 146 and 147.
- ENTRY2 = Entry # 147 = 4271
- ENTRY1 = Entry # 146 = 2416
- For a 50% level of interpolation: INTPFRC = 128 / 256 = \$80
- So:

AN1219 — Rev. 1.0

$$Y = 2416 + (128(4271 - 2416))/256$$

$$= 2416 + (128(1855))/256$$

$$= 2416 + 927$$

$$Y = 3343_{10}$$
 or \$D0F

Signed 16 x 16 multiply
     This routine multiplies the signed 16-bit number in INTACC1:INTACC1+1 by
     the signed 16-bit number in INTACC2:INTACC2+1 and places the signed 32-bit
     value in locations INTACC1:INTACC1+3 (INTACC1 = MSB:INTACC1+3 = LSB).

32 x 16 Unsigned Divide
     This routine takes the 32-bit dividend stored in INTACC1:INTACC1+3
     and divides it by the 16-bit divisor stored in INTACC2:INTACC2+1.
     The quotient replaces the dividend and the remainder replaces the divisor.

Table Lookup and Interpolation
     This subroutine performs table lookup and interpolation between two 16-bit
     dependent variables (Y) from a table of up to 256 enties (512 bytes) and
     allowing up to 256 interpolation levels between entries. INTACC1 contains
     the position of ENTRY2 and INTACC1+1 contains the interpolation fraction.
     The 16-bit result is placed in INTACC1+2=MSB, INTACC1+3=LSB. INTACC2 is
     used to hold the two 16-bit entries during the routine.
     Y = ENTRY1 + (INTPFRC(ENTRY2 - ENTRY1))/256
