Moreover, f_r is the solution of the extended Pearson system $G(r) f_{r+1} - L(r) f_r = 0, r = 0, 1, 2, \dots$

where functions
$$L$$
 and G are second-degree polynomials

$$G\left(r\right)=\left(\gamma+r\right)\left(r+1\right). \tag{2.2}$$
 From (2.1) Extends (1086) proved that non-control moments weifs the

 $L(r) = (\alpha + r)(\beta + r)\lambda$

(2.1)

From (2.1) Fajardo (1986) proved that non-central moments verify the recurrence equation

$$\mu'_{h+2} + (\gamma - 1) \, \mu'_{h+1} - \lambda \, \sum_{m=0}^{h} \, \binom{h}{m} \, \left[\mu'_{m+2} + (\alpha + \beta) \, \mu'_{m+1} + \alpha \beta \mu'_{m} \right] = 0,$$

 $\mu'_{h+2} + (\gamma - 1) \mu'_{h+1} - \lambda \sum_{m=0}^{n} \binom{h}{m} \left[\mu'_{m+2} + (\alpha + \beta) \mu'_{m+1} + \alpha \beta \mu'_{m} \right] = 0,$ (2.3)

for h = 0, 1, 2, ... if $\lambda < 1$ or the distribution is finite, and for h =0,1,2,...,k-2 if $\lambda=1$ and $\gamma>\alpha+\beta+k$ with $k\geq 2$. It is of note that this recurrence relation can not generally provide explicit expressions of moments from parameters, because n equations involve n+1 moments;

nevertheless, if $\lambda = 1$, n equations involve n moments which may be calculated as solutions of the corresponding linear system.
